# Online Appendix for Influencing Connected Legislators 

#### Abstract

In this appendix we present omitted proofs and tables for "Influencing Connected Legislators."

## 1 Proof of Lemma 1

Let $\varphi$ be the $n$ dimensional column vector of voting probabilities with $i$ th element equal to $\varphi_{i}$. Define $\boldsymbol{\eta}: R^{n} \rightarrow R^{n}$ as $\boldsymbol{\eta}(\boldsymbol{\varphi}, \mathbf{s})=\boldsymbol{\varphi}-\mathbf{F}(\boldsymbol{\varphi}, \mathbf{s})$, where $\mathbf{s}=\left(\mathbf{s}_{\mathbf{A}}, \mathbf{s}_{\mathbf{B}}\right)$ and $\mathbf{F}(\boldsymbol{\varphi}, \mathbf{s})$ is a column vector with $i$ th element equal to $1 / 2+\Psi\left(\omega\left(s_{A}^{i}\right)-\omega\left(s_{B}^{i}\right)+v^{i} q^{i}(\boldsymbol{\varphi})+\phi \sum_{j} g_{i, j}\left(2 \varphi_{j}-1\right)\right)$, as defined in (5) in Section 3.1. The equilibrium probabilities $\boldsymbol{\varphi}(\mathbf{s})$ are defined as the solution of $\boldsymbol{\eta}\left(\boldsymbol{\varphi}^{*}, \mathbf{s}\right)=0$. The fact that the solution of this system exists follows from Brouwer's fixed-point theorem as argued in Section 3. Since, by Assumption 1, $\Psi(\bar{v}+\phi+\omega(2 W))<1 / 2$, the solution is interior in $(0,1)$. To show uniqueness of an equilibrium of the voting stage with policy motivated legislators for $\Psi$ sufficiently small, let $\|x\|$ be the norm $\|x\|=\sum_{i}\left|x_{i}\right|$ for any $x \in R^{n}$. We have:

$$
\begin{aligned}
\left\|\mathbf{F}(\boldsymbol{\varphi}, \mathbf{s})-\mathbf{F}\left(\boldsymbol{\varphi}^{\prime}, \mathbf{s}\right)\right\| & \leq \Psi\left(\bar{\nu} \cdot \sum_{l}\left|\int_{\varphi_{l}^{\prime}}^{\varphi_{l}} \sum_{i} q_{l}^{i}(\mathbf{x})\right| d x+2 \phi \sum_{j}\left(\sum_{i} g_{i, j}\right)\left|\varphi_{j}-\varphi_{j}^{\prime}\right|\right) \\
& \leq \Psi\left(n \bar{\nu} \cdot \sum_{l}\left(\left|\varphi_{l}-\varphi_{l}^{\prime}\right|\right)+2 \phi \sum_{j}\left|\varphi_{j}-\varphi_{j}^{\prime}\right|\right) \leq \Psi(n \bar{v}+2 \phi)\left\|\varphi-\boldsymbol{\varphi}^{\prime}\right\|
\end{aligned}
$$

where we use the fact that $\left|q_{j}^{i}(\mathbf{x})\right|<1$ for any $\mathbf{x}$, and $\sum_{i} g_{i, j} \leq 1$ for any $j$. For any $\eta<1$, we therefore have $\left\|\mathbf{F}(\boldsymbol{\varphi}, \mathbf{s})-\mathbf{F}\left(\boldsymbol{\varphi}^{\prime}, \mathbf{s}\right)\right\| \leq \eta \cdot\left\|\varphi-\boldsymbol{\varphi}^{\prime}\right\|$ for $\Psi$ sufficiently small. We can therefore conclude that there is a $\Psi_{1}$ such that $\mathbf{F}(\boldsymbol{\varphi}, \mathbf{s})$ is a contraction in $[0,1]$ with a unique fixed-point in $(0,1)$ for $\Psi \leq \Psi_{1}$.

We now turn to the derivatives of the voting probabilities. The implicit function theorem implies that the solution $\varphi_{i}$ is differentiable in $s_{A}^{j}$ at $\mathbf{s}_{A}, \mathbf{s}_{B}$ if $(D \boldsymbol{\eta})_{\varphi}$ is invertible in a neighborhood of $\left(\mathbf{s}_{A}, \mathbf{s}_{B}, \boldsymbol{\varphi}\left(\mathbf{s}_{\mathbf{A}}, \mathbf{s}_{\mathbf{B}}\right)\right)$, where $\boldsymbol{\varphi}\left(\mathbf{s}_{\mathbf{A}}, \mathbf{s}_{\mathbf{B}}\right)$ solves $\boldsymbol{\eta}\left(\boldsymbol{\varphi}, \mathbf{s}_{A}, \mathbf{s}_{B}\right)=0$ (the expression $(D \boldsymbol{\eta})_{\boldsymbol{\varphi}}$ represents the Jacobian of $\boldsymbol{\eta}$ with respect to $\boldsymbol{\varphi}$ ). It is easy to verify that $(D \boldsymbol{\eta})_{\boldsymbol{\varphi}}=[I-\phi \Psi 2 \widetilde{G}]$, where $\widetilde{G}$ is a $n \times n$ matrix with $i, j$ element equal to $\widetilde{g}_{i, l}=g_{i, l}\left(g_{i, l}+v^{i} q_{l}^{i}(\boldsymbol{\varphi})\right)$. Let $r^{*}$ be the largest eigenvalue of $\widetilde{G}$ achieved for some $\varphi$ (this is well defined and bounded since $r(\widetilde{G})$ is continuos in $\varphi$ in and the space of feasible $\varphi$ is compact). Theorem III* of Debreu and Herstein [1953] implies that $[I-\phi \Psi 2 \widetilde{G}]^{-1}$ exists and is nonegative for $\Psi \leq\left(2 \phi r^{*}\right)^{-1}=\Psi_{2}$. The Jacobian of $\varphi$ is then

$$
D_{j}[\varphi]=\Psi \cdot \omega^{\prime}\left(s_{A}^{l}\right)[I-\phi \Psi 2 \widetilde{G}]^{-1} \mathbf{1}_{j}
$$

where $\mathbf{1}_{j}$ is a $n$-dimensional vector equal to zero except at the $i$ th dimension in which it is equal to one. Since $[I-\phi \Psi 2 \widetilde{G}]^{-1}$ is nonnegative with at least one strictly positive element for $\Psi \leq \Psi_{2}$, it follows that $\sum_{i} \partial \varphi_{i} / \partial s_{A}^{j}=D_{j}[\varphi]^{T} \cdot \mathbf{1}>0$ for $n$ large enough.

To verify concavity with respect to $\mathbf{s}_{A}$, let $D^{2} \varphi_{i}$ be the Hessian of $\varphi_{i}$. Consider first its diagonal entries $\partial^{2} \varphi_{i} / \partial s_{A}^{j} \partial s_{A}^{j}$ for any $j$. We can write:

$$
\frac{\partial^{2} \varphi_{i}}{\partial s_{A}^{j} \partial s_{A}^{j}}=\Psi\left[\begin{array}{c}
\frac{\partial^{2} \omega_{j}\left(s_{A}^{i}\right)}{\partial s_{A}^{j} \partial s_{A}^{j}}+2 \phi \sum_{l} g_{i, l} \frac{\partial^{2} \varphi_{l}}{\partial s_{A}^{j} \partial s_{A}^{j}}  \tag{1}\\
+v^{i} \sum_{l}\left(\sum_{k} q_{l k}^{i}(\varphi)\left(\frac{\partial \varphi_{l}}{\partial s_{A}^{j}}\right)\left(\frac{\partial \varphi_{k}}{\partial s_{A}^{j}}\right)+q_{l}^{i}(\varphi) \frac{\partial^{2} \varphi_{l}}{\partial s_{A}^{j} \partial s_{A}^{j}}\right)
\end{array}\right]
$$

We can write:

$$
\begin{equation*}
[I-\phi \Psi 2 \widetilde{G}]\left(D^{2} \boldsymbol{\varphi}\right)_{j j}=\Psi \omega^{\prime \prime}\left(s_{A}^{l}\right)\left(\mathbf{1}_{j}+\Psi^{2} \frac{\left(\omega^{\prime}\left(s_{A}^{l}\right)\right)^{2}}{\omega^{\prime \prime}\left(s_{A}^{l}\right)} V\left(\mathbf{z}^{j}\right)^{T} D^{2} q^{i}(\boldsymbol{\varphi})\left(\mathbf{z}^{j}\right)\right) \tag{2}
\end{equation*}
$$

where $\left(D^{2} \boldsymbol{\varphi}\right)_{j j}=\left(\frac{\partial^{2} \varphi_{1}}{\partial s_{A}^{j} \partial s_{A}^{j}}, \ldots, \frac{\partial^{2} \varphi_{n}}{\partial s_{A}^{j} \partial s_{A}^{j}}\right)^{T}$, the $n \times n$ matrix $D^{2} q^{i}(\boldsymbol{\varphi})$ is the Hessian of $q^{i}(\boldsymbol{\varphi})$, and $\mathbf{z}^{j}=$ $[I-\phi \Psi 2 \widetilde{G}]^{-1} \mathbf{1}_{j}$. The Hessian $\left(D^{2} \boldsymbol{\varphi}\right)_{j j}$ exists if $[I-\phi \Psi 2 \widetilde{G}]$ is invertible: a property that, as shown above, is verified if $\Psi \leq \Psi^{*}$. Since $\left(\omega^{\prime}\left(s_{A}^{l}\right)\right)^{2} / \omega^{\prime \prime}\left(s_{A}^{l}\right)$ is bounded for any feasible $s_{A}^{l}$, and $\mathbf{z}^{j}$ is a positive column vector with $l$ element $z_{l}^{j} \leq \bar{z}$ for some finite $\bar{z}$, the $i$ th term of the second term in the parenthesis in the right hand side of (2) is bounded above by $\Psi^{2} \frac{\omega^{\prime \prime}\left(s_{A}^{l}\right)}{\omega^{\prime}\left(s_{A}^{l}\right)} \overline{v z}^{2} \sum_{v} \sum_{k} q_{v, k}^{i}(\boldsymbol{\varphi})$. It follows that:

$$
\begin{equation*}
\left(D^{2} \varphi\right)_{j j}=[I-\phi \Psi 2 \widetilde{G}]^{-1} \Psi \omega^{\prime}\left(s_{A}^{l}\right)\left(\mathbf{1}_{j}+o\left(\Psi^{2}\right)\right) \tag{3}
\end{equation*}
$$

where $o\left(\Psi^{2}\right)$ converges to zero as $\Psi \rightarrow 0$ at the speed of $\Psi^{2}$. By the fact that $[I-\phi \Psi 2 \widetilde{G}]^{-1}$ is positive and $\omega^{\prime \prime}\left(s_{A}^{l}\right)<0$, it follows that $\sum_{i} \partial^{2} \varphi_{i} / \partial s_{A}^{j} \partial s_{A}^{j}=\left(D^{2} \varphi\right)_{j j} \cdot 1<0$ for a sufficiently small $\Psi$. We conclude that the diagonal of the Hessian of $\sum_{i} \varphi_{i}$ has all strictly negative values. Following the same steps as above it we can also show that for any $\varepsilon$ there is a $\Psi_{3}$ such that the absolute values of the off diagonal elements of the Hessian of $\sum_{i} \varphi_{i}$ are lower than $\varepsilon$ for $\Psi \leq \Psi_{3}$. This implies that there is a $\Psi^{*}$ such that $\sum_{i} \varphi_{i}$ is increasing and strictly concave in respectively $s_{A}^{j}$ and $\mathbf{s}_{A}$ for $\Psi \leq \Psi^{*}$.

## 2 Proof of Lemma 3.1

The fact that all agents of the same type have the same Bonacich centrality is immediate from the definition. We can write:

$$
b_{i}\left(\phi^{*}, G^{T}\right)=1+\phi^{*} \sum_{l=1}^{n} g_{l, i} \cdot b_{l}\left(\phi^{*}, G^{T}\right)=1+\phi^{*} \sum_{\tau=1}^{m} n_{\tau} h_{\tau, l(i)} \cdot \bar{b}_{\tau}
$$

where $\bar{b}_{\tau}$ be the Bonacich centrality of an agent of type $\tau$. Since, again, $b_{i}\left(\phi^{*}, G\right)=\bar{b}_{\iota(i)}$, we have: $\bar{b}_{\iota(i)}=1+\phi^{*} \sum_{\tau=1}^{m} \widetilde{h}_{\tau, \iota(i)} \cdot \bar{b}_{\tau}$ where $\widetilde{h}_{i, j}=n_{\tau} h_{\tau, \iota(i)}=\alpha_{j} h_{i, j} /\left(\sum_{l} \alpha_{l} h_{i, l}\right)$, since $\sum_{l} \alpha_{l} h_{i, l}=$ $\sum_{l} g_{i, l} / n=1 / n$. We therefore have that $\overline{\mathbf{b}}=\left[I+\phi^{*} \widetilde{H}^{T}\right]^{-1} \cdot \mathbf{1}$, implying that $b_{i}\left(\phi^{*}, G\right)$ is defined by (30) as stated.

## 3 Proof of Lemma 3.2

We first note that by Assumption $1 \varphi_{j} \leq \bar{\varphi}, \varphi_{j} \geq \underline{\varphi}$ for some $\bar{\varphi}$ and $\underline{\varphi}$ in $(0,1)$, any legislator $j$ and any $\mathbf{s}_{A}, \mathbf{s}_{B}$. Given this, we proceed in two steps.

Step 1. We prove here that $\lim _{n \rightarrow \infty} q^{n, j}=0$ for all $j=1, \ldots, n$. Consider the pivot probability of a player $j$ of type $i$. There are two cases to consider.

Case 1.1. Suppose first that $\alpha_{i}^{n} \rightarrow \alpha_{i}>0$. Let $M_{-i}^{n}$ be the profile of votes of all types different from $i$. Let $P_{i}^{n}$ be the probability that there is a profile of votes $M_{-i}^{n}$ such that $j$ can be pivotal for some profile $m_{i}^{-j, n}$ of players of type $i$ different than $j$. Let $p_{j}^{n}\left(M_{-i}^{n}\right)$ be the probability of $m_{i}^{-j, n}$ such that $j$ is pivotal given $M_{-i}^{n}$ and let $\bar{p}_{j}^{n}=\max _{M_{-i}^{n}} p_{j}\left(M_{-i}^{n}\right)$. Associated to $\bar{p}_{j}^{n}$ there is a number $\widehat{l}{ }_{j}^{n}$ of legislators of type $i$ that must vote for $A$ in order for $j$ to be pivotal. Let $\eta_{j}^{n}=\widehat{l}_{j}^{n} /\left(n_{i}-1\right)$ the share of types $i$ other than $j$ that are needed to make $j$ pivotal. If $\eta_{j}^{n} \rightarrow 1$ or $\eta_{j}^{n} \rightarrow 0$ then $\bar{p}_{j}^{n}$ converges to zero, so $j$ 's pivot probability converges to zero. Assume $\eta_{j}^{n} \rightarrow \eta_{j} \in(0,1)$. Given this, $j$ 's pivot probability can be bounded above as follows. To keep the formulas simple, let $z_{i}(n)=\alpha_{i} n-1$

$$
\begin{aligned}
\lim _{n \rightarrow \infty} q^{n, i} & \leq P_{i}^{n} \cdot \lim _{n \rightarrow \infty} b\left(\eta_{j}^{n} z_{i}(n) ; z_{i}(n), \varphi^{i}\right) \\
& \leq \lim _{n \rightarrow \infty}\binom{z_{i}(n)}{\eta_{j}^{n} z_{i}(n)}\left(\left(\varphi^{i}\right)^{\eta_{j}^{n} z_{i}(n)} \cdot\left(1-\varphi^{i}\right)^{\left(1-\eta_{j}^{n}\right) z_{i}(n)}\right) \\
& \leq \lim _{n \rightarrow \infty} \frac{\left(\sqrt{2 \pi z_{i}(n)} \cdot\left(z_{i}(n)\right)^{z_{i}(n)} e^{-z_{i}(n)}\right) \cdot\left(\left(\varphi^{i}\right)^{\eta_{j}^{n} z_{i}(n)} \cdot\left(1-\varphi^{j}\right)^{\left(1-\eta_{j}^{n}\right) z_{i}(n)}\right)}{\left(\sqrt{2 \pi \eta_{j}^{n} z_{i}(n)} \cdot\left(\eta_{j}^{n} z_{i}(n)\right)^{\eta_{j}^{n} z_{i}(n)} e^{-\eta_{j}^{n} z_{i}(n)}\right)} \\
& \left.=\sqrt{2 \pi\left(1-\eta_{j}^{n}\right) z_{i}(n)} \cdot\left(\left(1-\eta_{j}^{n}\right) z_{i}(n)\right)^{\left(1-\eta_{j}^{n}\right) z_{i}(n)} e^{-\left(1-\eta_{j}^{n}\right) z_{i}(n)}\right) \\
& =\lim _{n \rightarrow \infty} \frac{1}{\left(\left(\sqrt{2 \pi \eta_{j}^{n}}\right) \cdot \sqrt{\left(1-\eta_{j}^{n}\right)}\right)} \cdot\left(\frac{\left(\left(\varphi^{i}\right)^{\eta_{j}^{n}} \cdot\left(1-\varphi^{j}\right)^{1-\eta_{j}^{n}}\right)}{\left.\left(\eta_{j}^{n}\right)^{\eta_{j}^{n}}\left(1-\eta_{j}^{n}\right)^{1-\eta_{j}^{n}}\right)}\right)^{z_{i}(n)} \cdot \frac{1}{\sqrt{z_{i}(n)}} \\
& \leq \frac{1}{\left(\left(\sqrt{2 \pi \eta_{j}}\right) \cdot \sqrt{\left(1-\eta_{j}\right)}\right)} \lim _{n \rightarrow \infty} \frac{1}{\sqrt{z_{i}(n)}}=0,
\end{aligned}
$$

where the third inequality follows from the Stirling formula and the last follows from the fact that $\eta_{j}^{n} \in \arg \max _{\varphi}\left((\varphi)^{\eta_{j}^{n}}(1-\varphi)^{1-\eta_{j}^{n}}\right)$.
Case 1.2. Consider now that case in which $\alpha_{i}^{n} \rightarrow 0$. Let $M_{-j k}^{n}$ the profile of votes of: 1) all types $i$ but different than agent $j$; and 2) of all other types $t \neq i, k$, where $k$ is a type such that $\alpha_{k}^{n} \rightarrow \alpha_{k}>0$. Let $P_{-j k}^{n}$ be the probability that there is a profile of votes $M_{-j k}^{n}$ such that $j$ can be pivotal for some profile $m_{k}^{n}$ of players in $k$. Let $p_{j}^{n}\left(M_{-j k}\right)$ be the probability of $m_{k}^{n}$ such that $j$ is pivotal given $M_{-j k}$ and let $\bar{p}_{j}^{n}=\max _{M_{-j k}^{n}} p_{j}\left(M_{-j k}^{n}\right)$. As above the pivot probability $q^{n, i}$ can be bounded above by $P_{-j k}^{n} \cdot \bar{p}_{j k}^{n}$. Proceeding as in the previous case, we can prove that this upper bound converges to zero as $n \rightarrow \infty$, implying the result.
Step 2. Consider now $\sum_{j}\left|q_{j}^{n, i}\right|$. For any two distinct legislators $i$ and $j$, let $N^{-i j}$ and $\boldsymbol{\varphi}^{-i j}$ be, respectively, the set of all legislators except $i$ and $j$ and the associated vector of probabilities of choosing $P$. Let moreover $S\left(N^{-i}, s\right)$ be the set of all $s$-combinations of $N^{-i j}$. We have that for
any $j \neq i, q^{n, i}=\varphi_{j} E_{n}+\left(1-\varphi_{j}\right) F_{j}$ where:

$$
\begin{aligned}
E_{n} & =\sum_{A \in S\left(N^{-i j}, q n-2\right)} \prod_{k \in A} \varphi_{k}^{-i j} \cdot \prod_{l \in A^{C}}\left(1-\varphi_{l}^{-i j}\right) \\
F_{n} & =\sum_{A \in S\left(N^{-i j}, q n-1\right)} \prod_{k \in A}\left(\varphi_{k}^{-i j}\right) \cdot \prod_{l \in A^{C}}\left(1-\varphi_{l}^{-i j}\right)
\end{aligned}
$$

We can therefore write: $q_{j}^{n, i}=\left(E_{n}-F_{n}\right)$. From Step 1 we know that $q^{n, i} \rightarrow 0$ as $n \rightarrow \infty$ for all i. It follows from (5) in Section 3.1, that $\varphi_{i} \rightarrow 1 / 2$ for all legislators. This implies that, for all $i,\left|E_{n}-F_{n}\right|$ can be bounded above by: $K_{n}=\Theta\binom{n}{q n}((1+\delta) / 2)^{n}$ where $\Theta>1$, and $\delta>0$ is a parameter that can be chosen arbitrarily close to 0 for $n$ sufficiently large. It follows that $\sum_{j}\left|q_{j}^{n, i}\right|$ is bounded above by $n K_{n}$. Using again the Stirling formula we have:

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} n K_{n}=\lim _{n \rightarrow \infty} \frac{n \Theta \sqrt{2 \pi n} n^{n} e^{n}}{\left[\begin{array}{c}
\sqrt{2 \pi q n}(q n)^{q n} e^{q n} . \\
\sqrt{2 \pi(1-q) n}[(1-q) n]^{(1-q) n} e^{(1-q) n}
\end{array}\right]}((1+\delta) / 2)^{n} \\
= & \frac{\Theta}{\sqrt{2 \pi q(1-q)}} \lim _{n \rightarrow \infty}\left(n^{1 / 2}\left(\frac{2 \cdot q^{q}(1-q)^{1-q}}{1+\delta}\right)^{-n}\right)=\frac{\Theta}{\sqrt{2 \pi q(1-q)}} \lim _{n \rightarrow \infty}\left(n^{1 / 2}(1-\epsilon)^{n}\right)
\end{aligned}
$$

for some $\epsilon>0$, where the last equality follows from the fact since, $\delta$ is arbitrarily small, 2 . $q^{q}(1-q)^{1-q} /(1+\delta)>1$ for any $q \in(1 / 2,1)$. Since $\lim _{n \rightarrow \infty}\left(n^{1 / 2}(1-\epsilon)^{n}\right)=0$, we have that $\sum_{j}\left|q_{j}^{n, i}\right|$ converge to zero.

## 4 Derivation of Equation 19 in Section 4.1

The necessary and sufficient condition (17) in Section 4.1 for interest group $l=A, B$ is

$$
\sum_{j}\left(\partial \varphi_{j}\left(\mathbf{s}_{A}, \mathbf{s}_{B}\right) / \partial s_{l}^{i} \cdot \theta_{j}\right)=\lambda
$$

where $\lambda$ is the Lagrangian multiplier associated to the constraint. In matrix form as $D \boldsymbol{\varphi}^{T} \cdot \boldsymbol{\theta}=\lambda$ and using (9) in Section 3.2, we have:

$$
\begin{equation*}
D \boldsymbol{\varphi}^{T} \cdot \boldsymbol{\theta}=\Psi \cdot D \boldsymbol{\omega}^{T} \cdot\left(I-\phi^{*} \cdot G^{T}\right)^{-1} \boldsymbol{\theta}=\lambda \tag{4}
\end{equation*}
$$

Let $\mathbf{b}^{\theta}\left(\boldsymbol{\phi}^{*}, \mathbf{G}\right)=\left(I-\phi^{*} \cdot G^{T}\right)^{-1} \cdot \boldsymbol{\theta}$ be the weighted Bonacich centrality measure, with $\mathbf{b}^{\theta}\left(\boldsymbol{\phi}^{*}, \mathbf{G}\right)=$ $\left(b_{1}^{\theta}\left(\phi^{*}, G\right), \ldots, b_{n}^{\theta}\left(\phi^{*}, G\right)\right)$. The first order condition (4) can then be written as: $b_{j}^{\theta}\left(\phi^{*}, G\right) \omega\left(s_{A}^{j}\right)=$ $\lambda_{*}$, where $\lambda_{*}=\lambda / \Psi$.

## 5 Proof of the result stated in Section 5.3

Let us define $\beta_{l}^{n}\left(s_{A}, s_{B}\right)$ as the probability that threshold $l$ is passed for $l=1, \ldots, J, \beta_{l}^{n}\left(s_{A}, s_{B}\right)=$ $\operatorname{Pr}\left(\sum_{i} x_{i}^{n}(A)>z_{l} \mid \mathbf{s}_{A}, \mathbf{s}_{B}\right)$. With preferences that depend on reaching the threshold $z_{j}$, interest group $A$ 's expect utility can be written as: $W_{n}^{\mathbf{z}, \mathbf{u}}\left(\mathbf{s}_{A}, \mathbf{s}_{B}\right)=u_{0}+\sum_{l=0}^{J}\left(u_{l}-u_{l-1}\right) \beta_{l}^{n}\left(\mathbf{s}_{A}, \mathbf{s}_{B}\right)$. The equilibrium contributions are characterized by the first order necessary condition of:

$$
\begin{equation*}
\max _{\left(\mathbf{s}_{A}, \mathbf{s}_{B}\right) \in S} W_{n}^{\mathbf{z}, \mathbf{u}}\left(\mathbf{s}_{A}, \mathbf{s}_{B}\right) \tag{5}
\end{equation*}
$$

The necessary condition of the corresponding Lagrangian with respect to $s_{A}^{j}$ where $j$ is an agent of type $i$ :

$$
\begin{equation*}
\frac{\partial W_{n}^{\mathbf{z}, \mathbf{u}}\left(\mathbf{s}_{A}, \mathbf{s}_{B}\right)}{\partial s_{A}^{j}}=\sum_{k}\left(\sum_{l}\left(u_{l}-u_{l-1}\right) \frac{\partial \beta_{l}^{n}}{\partial \varphi_{k}}\right) \cdot \frac{\partial \varphi_{k}^{n}}{\partial s_{A}^{j}}=\lambda^{n} \tag{6}
\end{equation*}
$$

where $\partial \beta_{l}^{n} / \partial \varphi_{k}$ and $\partial \varphi_{k}^{n} / \partial s_{A}^{j}$ are the derivatives of $\beta_{l}^{n}\left(s_{A}, s_{B}\right)$ and $\varphi_{k}^{n}\left(s_{A}, s_{B}\right)$ with respect to, respectively, $\varphi_{k}^{n}$ and $s_{A}^{n, j}$ evaluated at $\widetilde{\mathbf{s}}$ and $\lambda^{n}$ is chosen to satisfy the budget constraint. It is easy to verify that $\partial \beta_{l}^{n} / \partial \varphi_{k}$ is equal to the probability that legislator $k$ is "pivotal" in having threshold $l$ passed, that is $\partial \beta_{l}^{n} / \partial \varphi_{k}=\beta_{l}^{-k, n}$ where $\beta_{l}^{-k, n}=\operatorname{Pr}\left(\sum_{i \neq k} x_{i}^{n}(A)=z_{l} \mid \mathbf{s}_{*}, \mathbf{s}_{*}\right)$. We can rewrite (6) as:

$$
\frac{\sum_{k=1}^{n}\left(R_{k}^{n} / R_{1}^{n}\right) \cdot \partial \varphi_{k}^{n} / \partial s_{A}^{j}}{\sum_{k=1}^{n}\left(R_{k}^{n} / R_{1}^{n}\right) \cdot \partial \varphi_{k}^{n} / \partial s_{A}^{l}}=1
$$

where $R_{k}^{n}=\sum_{l}\left[\left(u_{l}-u_{l-1}\right) \cdot \partial \beta_{l}^{n} / \partial \varphi_{k}\right]$. Note that, by Lemma 3.2, $q_{n}^{i} \rightarrow 0$ as $n \rightarrow \infty$, so by (5) in section 3.1 we must have that the probability that $i$ votes for $A$ is $\varphi_{i, n} \rightarrow 1 / 2$ as $n \rightarrow \infty$. This implies that $\beta_{l}^{-k} / \beta_{1}^{-k} \rightarrow 1$ and so $R_{j}^{n} / R_{1}^{n} \rightarrow 1$ for any $j=1, . ., m$. It follows that

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \frac{\sum_{k=1}^{n}\left(R_{k}^{n} / R_{1}^{n}\right) \cdot \partial \varphi_{k}^{n} / \partial s_{A}^{j}}{\sum_{k=1}^{n}\left(R_{k}^{n} / R_{1}^{n}\right) \cdot \partial \varphi_{k}^{n} / \partial s_{A}^{l}} & =\lim _{n \rightarrow \infty} \frac{\sum_{k=1}^{n} \partial \varphi_{k}^{n} / \partial s_{A}^{j}}{\sum_{k=1}^{n} \partial \varphi_{k}^{n} / \partial s_{A}^{l}}=\lim _{n \rightarrow \infty} \frac{b_{j}^{\mathcal{M}}\left(\phi^{*}, V, G^{T}\right) \omega^{\prime}\left(s_{A}^{j}\right)}{b_{l}^{\mathcal{M}}\left(\phi^{*}, V, G^{T}\right) \omega^{\prime}\left(s_{A}^{l}\right)} \\
& =\lim _{n \rightarrow \infty} \frac{b_{j}\left(\phi^{*}, G^{T}\right)}{b_{l}\left(\phi^{*}, G^{T}\right)} \frac{\omega^{\prime}\left(s_{A}^{j}\right)}{\omega^{\prime}\left(s_{A}^{l}\right)}=1 \quad \forall j, l
\end{aligned}
$$

where the second equality follows from the analysis of $D \varphi^{T} \cdot 1$ in Section 7.2 and $\left(b_{i}\left(\phi^{*}, G^{T}\right)\right)_{i=1}^{n}$ are the limit Bonacichs. We conclude that for a large $n$, we have $\frac{\omega^{\prime}\left(s_{A}^{j}\right)}{\omega^{\prime}\left(s_{A}^{l}\right)} \simeq \frac{b_{l}\left(\phi^{*}, G^{T}\right)}{b_{j}\left(\phi^{*}, G^{T}\right)}$, or $b_{j}\left(\phi^{*}, G^{T}\right) \omega^{\prime}\left(s_{A}^{j}\right) \simeq \lambda$ for all $j=1, \ldots, n$. Assuming log utility as in Section 4 of the paper, we have $s_{A}^{j} \simeq b_{j}\left(\phi^{*}, G^{T}\right)$ for all $j=1, \ldots, n$.

Notes: ML estimated coefficients and standard errors (in parentheses) are reported. In column (7) standard errors are bootstrapped with 1000 replications. A precise definition of control variables can be found in Table A.1. ${ }^{*}$, ${ }^{* *}$, ${ }^{* * *}$ indicate statistical significance at the 10,5 and 1 percent levels.
